

XX. NWA 856

Basalt
320 grams

Figure XX-1: Photograph of NWA 856 (Djel Ibone) kindly provided by Bruno Fectay and Carine Bidaut illustrating thin fusion crust and interior basaltic texture (scale is 1 cm).

Introduction

Jambon *et al.* (2001, 2002) describe the discovery in March 2001 of another basaltic shergottite from Morocco. This sample was originally referred to as “Djel Ibone” and is officially known as NWA 856 (Russell *et al.* 2002). The original piece (~ 5 cm) had a thin black fusion crust that was well preserved – see also figure 1 in Jambon *et al.* (2002).

Petrography

This meteorite is a fine-grained basalt (figure XX-1) with gray acicular pyroxene phenocrysts up to 12 mm long (Jambon *et al.* 2002). Augite and pigeonite form as separate crystals. Plagioclase (maskelynite) laths are interstitial as is trace merrillite, apatite, pyrrhotite, chromite, Fe-Ti oxides, silica and baddeleyite.

Shock melt pockets are more abundant than in Shergotty or Zagami and this meteorite is highly fractured at all scales.

Mineralogical Mode

	Jambon <i>et al.</i> 2002
Pyroxene	68 vol. %
Plagioclase	23
Phosphates	1
Oxides	2
Silica	1
Melt Pockets	2

Terrestrial calcite veins cross-cut this meteorite, but terrestrial weathering appears to be at a minimum because Cs, Ba, Sr and U are not elevated (Jambon *et al.* 2002).

Photos can also be seen at <http://www.jpl.nasa.gov/snc/nwa856.html>

Mineral Chemistry

Pyroxenes: As in the Shergotty meteorite, augite and pigeonite are present in NWA 856 as separate phases, with no pyroxenes of intermediate composition (figure XX-2). Pyroxenes are zoned; pigeonite ranges from $\text{En}_{59}\text{Fs}_{29}\text{Wo}_{12}$ to $\text{En}_{26}\text{Fs}_{59}\text{Wo}_{15}$ and augite from $\text{En}_{36}\text{Fs}_{32}\text{Wo}_{32}$ to $\text{En}_{48}\text{Fs}_{39}\text{Wo}_{13}$.

Figure XX-2: Pyroxene composition diagram for NWA 856 (data replotted from Jambon *et al.* 2002).

Maskelynite: Plagioclase has been shocked to maskelynite $\text{Ab}_{48}\text{Or}_2\text{An}_{50}$.

Phosphates: Both merrillite and Cl-apatite are present.

Stishovite: Relative abundant and large euhedral crystals or thin square needles of stishovite have been observed by Raman spectroscopy (Jambon *et al.* 2002) in melt pockets of NWA 856.

Baddelyite: Two minute baddelyite crystals are reported.

Amphibole: Minute amphibole is reported by Jambon *et al.* (2002) located in melt inclusions in pyroxene cores.

Whole-rock Composition

Table XX-1 gives the composition of NWA 856 as reported by Jambon *et al.* (2001, 2002). The REE pattern of NWA 856 is similar to those of Shergotty and Zagami (figure XX-3). The Ga/Al ratio (4.1×10^{-4}) indicates that this rock is Martian. Weathering does not appear to have left a significant chemical signature in this desert meteorite (Jambon *et al.* 2002).

Other Isotopes

Jambon *et al.* (2001, 2002) reported oxygen isotopes with $\Delta^{17}\text{O} = \sim 0.47 \text{ ‰}$.

Figure XX-3: Normalized rare earth element diagram for NWA 856 compared with that of Shergotty (data from Jambon *et al.* 2002 and Lodders 1998).

Processing

Figure XX-4 shows details of a slab of NWA 856.

Figure XX-4: Close up of slab of Djel Ibone illustrating basaltic texture (whose nice clean fingers?).

Table XX-1: Chemical composition of NWA 856.
